CREATION OF LASER ENRICHMENT LABORATORY IN IRAN: A TRUE STORY OF JEFF EERKENS*¹

Anton Khlopkov**

When the laser was invented in the 1960s, research immediately began into its possible military and civilian applications.² First came the pulsed lasers, which relied on an artificially grown ruby crystal as the active element; gas-discharge tubes were used for pumping excitation. Numerous other types of lasers were developed in later years, including gas lasers (which use inert gases, metal vapor, carbon dioxide, etc.). One of the first areas of research into commercial application of lasers was uranium enrichment. In the Soviet Union this research began in 1967 at the Kurchatov Atomic Energy Institute (now known as the Kurchatov Institute).³ In the United States, the Lawrence Livermore National Laboratory was the first to start developing laser separation of uranium isotopes in the early 1970s.⁴ In France a similar project started in the early 1980s.

The Iranian laser enrichment program: the first steps

Iran launched an ambitious nuclear energy program in 1974. It was one of the first countries to begin comprehensive research into using lasers for uranium isotope separation. The Iranians began to explore the possible uses of lasers in the early 1960s.⁵ In the spring of 1975 the Laser Technology Division at the Tehran Nuclear Research Center (TNRC) was set up. The division was to be given a newly-built 1,000 square feet research facility. The plan was to explore the technology of atomic vapor laser isotope separation (AVLIS) and molecular laser isotope separation (MLIS). As part of the AVLIS project, in 1975 the AEIOI signed a contract with a West German company to establish a laboratory to study the spectroscopic behavior of uranium metal.⁶ An order for some of the equipment for the laboratory was placed with Britain's Lintott Engineering Limited.⁷ Speaking at an international conference on the transfer of nuclear technologies held in April 1977 in Persepolis and Shiraz, Iranian scientists reported that they had independently developed and manufactured carbon dioxide (CO₂) lasers with an output of 6W.

* This article was drafted as part of the author's work on a monograph on the history of nuclear technology development in Iran. The article will be published in the upcoming issue of the Nuclear Club journal.

** Anton **Khlopkov** is the Director of the Moscow-based Center for Energy and Security Studies (CENESS), and Editor-in-Chief of the Nuclear Club journal. He is the author and co-author of a series of publications on Iran's nuclear program, including 'The Bushehr NPP: Why Did It Take So Long?' (Nuclear Club journal, №1, 2010), 'At the Nuclear Threshold: The Lessons of North Korea and Iran for the Nuclear Non-Proliferation Regime' (Moscow: Publishing House EchoBook, 2007), and 'Iran's Nuclear Program in the Russia-US Relations' (Moscow, PIR Center, 2001).

Since the Iranians intended to develop a molecular laser isotope separation technology, which uses uranium hexafluoride (UF₆) in the process, the AEOI reached an agreement with South Africa to buy a uranium hexafluoride production technology.⁸ Under the plans approved by the Shah, Iran was to have 23 GW of nuclear energy generation capacity by 1994. In order to satisfy the projected demand of its future nuclear energy industry, in 1975 Iran acquired a 15-per-cent stake in the Rossing uranium mine in South Africa (the territory is now part of Namibia).⁹

The Tehran Nuclear Research Center hired its first four laser specialists – two Iranians, an Israeli and an American - in the second half of 1975.¹⁰ In 1977 the TNRC Laser Technology Division had 5 physicists with a PhD degree, 4 with a Master's degree, 6 undergraduate students and 4 technicians.¹¹ Several of the Iranians working at the division were MIT graduates.^{12,13} It was expected that the division's future staffing requirements would reach 20 man-years per annum. These positions were to be filled by inviting Iranian specialists working abroad, training specialists at the center's own laboratories¹⁴, and inviting the leading scientists from other countries, including Britain, Germany and the United States.¹⁵ Tehran also set up a special scholarships program for the Iranian laser specialists wishing to continue their education abroad and earn a PhD degree from the leading foreign universities, on the condition that those specialists return to Iran and continue to work in the laser field once they have completed their studies.¹⁶ For example, Iranian specialists studied at Heriot-Watt University in Edinburgh, one of the largest in the UK.¹⁷

As part of their research into molecular laser separation of uranium isotopes, TNRC relied on cooperation with Dr. Jeff Eerkens, a leading American specialist in the field. This paper tells the story of how that cooperation began, how it developed, and how it ended. It is based on numerous publications and interviews, drawing heavily on the author's personal interviews with Dr. Eerkens.

Jeff Eerkens: from Berkeley student to laser luminary

In the 1960s-1970s the US government regarded research into the various applications of lasers as an important priority. Jeff Eerkens, an American of Dutch descent, was one of the first American scientists to begin to study the possibility of using lasers for separating the isotopes of heavy elements. He was born in 1931 in Indonesia, a Dutch colony at the time, where his father was a physician. In 1950 he came to the United States to enroll at the newly-created Nuclear Engineering Department of the University of California, Berkeley. He graduated in 1957; three years later he received his PhD degree in Engineering.¹⁸ His PhD thesis focused on studying various chemical effects in fluids produced by uranium fission fragments.

Eerkens' interest in nuclear engineering largely stemmed from his childhood experiences. During World War II he spent three years in a Japanese concentration camp on Java, from which he was freed only after Japan capitulated. He believes that the use of nuclear weapons by the United States in Hiroshima and Nagasaki saved his life, and later fuelled his interest in nuclear engineering, which was to become central to his career.^{19,20}

He received his first job as a nuclear scientist in 1957, when he was completing his Master's course. He worked at the Engineering Field Station of the University of California-Berkeley, where he measured the efficiency of the separation of uranium isotopes using a variant of an enrichment technology developed by Becker in Germany (the so-called nozzle separation method).^{21,22} The project was commissioned by the U.S. Atomic Energy Commission (AEC).

During his PhD studies in 1957-1960 Eerkens worked as a nuclear reactor engineer and physicist-in-charge for Aerojet-General-Nucleonics (AGN). He received a license to operate the AGN-201 and AGN-211 research reactors and helped install these units for AGN at the University of Oklahoma (Norman) and Rice Institute University (Houston, Texas). As part of his work for AGN he also took part in designing mobile land-based (ML-1) and space-borne (SNAP, SPUR) nuclear reactors. In 1961 he became a US citizen, which gave him greater opportunities to participate in classified projects commissioned by the US government.²³

After completing his PhD studies Eerkens settled in California, where he worked for several leading American aerospace companies. In 1960 he joined Aerospace Corporation, where he specialized in nuclear rocket propulsion studies and was involved in space surveillance satellite programs. These programs included the development of the VELA family of satellites, designed specifically to monitor the Soviet Union's compliance with the Partial Nuclear Test Ban Treaty signed in Moscow on August 5, 1963. Eerkens also participated in the MIDAS missile attack early warning program²⁴ and the SAMOS space reconnaissance program.²⁵

In 1963 Eerkens joined the Northrop Space Laboratories (NSL), where he for the first time became involved in laser-related projects, becoming the chief of the laser systems branch.²⁶ In a space of just one year he managed to design, build and demonstrate the world's first working direct nuclear-pumped gas laser, powered by the TRIGA Mk F pulsed reactor.²⁷ But as a result of the growing costs of the war in Vietnam after a full-scale American intervention in the conflict in 1964, the US government had to cut spending on defense research projects, including space projects. In 1967 Northrop was forced to shut down its Space Labs. Eerkens and several of his colleagues were asked to join the electronics division within the company, which would have meant abandoning their laser research.

Eerkens and his colleagues decided instead to leave Northrop and to set up a new company, Xion, specializing in designing, manufacturing and selling lasers. But finding customers proved very difficult. After six months the partners decided to shut down their company and to become hired employees once again.

In 1967 N.K. Satyendra, an American scientist of Indian descent who had previously served as vice-president of Northrop Space Laboratories and was Eerkens's boss, learned that Jeff was once again looking for a job. He invited Eerkens to join his newly created Science and Technology Associates (S&T) company. S&T was set up after the closure of NSL; its main customer was the Department of Defense. Eerkens was therefore able to continue his laser research at the new company. One of the

projects involved analyzing the plumes of Soviet ballistic missiles and identifying the composition of their fuel by spectral measurements from satellites. He also explored the possibility of using lasers to probe rocket exhaust plumes and to propel air balloons on US reconnaissance missions over a Chinese missile testing range. It was during his time at S&T, in 1969, that Eerkens, who was looking into potential new applications for lasers, first thought of the possibility of using lasers to separate uranium isotopes, and made first theoretical calculations.²⁸ He focused on the molecular method of laser isotope separation of heavy elements, now known as MLIS; he believed that the method would be easier and cheaper to implement as, unlike the atomic vapor laser isotope separation technology (AVLIS), it did not involve aggressive substances such as metallic uranium vapor. During his time with S&T, Eerkens also initiated his first uranium laser enrichment patent applications.

A talented scientist and author of numerous research papers, Satyendra proved less successful as a businessman. In the late 1960s his company was standing on the verge of bankruptcy. He had to lay off workers, retaining only two employees (including Eerkens) to complete the existing contracts. But Eerkens also had to leave the company in 1970 after Satyendra, who was already depressed over his business woes, killed himself a few months after his wife filed for divorce.

Laser enrichment: Eerkens' first success

In April 1971, with the help of a recommendation from an S&T lawyer, Eerkens got a job with AiResearch Manufacturing Co., a division of Garrett corporation, which was one of America's leading aerospace companies at the time. In the early 1960s several US national laboratories and industrial corporations received contracts from the AEC²⁹ to develop gas centrifuge enrichment technology suitable for commercial-scale application. Garrett began developing such centrifuges as part of a classified project in 1961.³⁰ Eerkens was hired as a staff scientist to work on the gas centrifuge project for uranium enrichment and to explore laser enrichment.³¹ While at Garrett, he was also responsible for completing the Rocket Radiation Handbook³², a three-volume edition he started during his time in S&T; the project was commissioned by the US Air Force.

Eerkens shared his ideas about the potential of the molecular technology of laser separation with the top Garrett management; he lobbied for funding to be allocated to put these theories to the test. The AiResearch gas centrifuge program already involved two of the main components required by the experiments proposed by Eerkens: uranium hexafluoride and mass spectrometers, which were used to measure the level of uranium enrichment. The funding Eerkens was asking for was therefore quite moderate; the only expensive part was to design and manufacture the actual lasers. The company gave his proposals the go-ahead, and Eerkens was appointed manager of the laser enrichment project, while at the same time continuing his work on the gas centrifuge. He also secured an agreement with the company to share the rights to any inventions made in the process.

In 1972-1973 Eerkens built and operated an experimental laser enrichment unit, which he used to investigate isotope-selective laser enhancement of slow chemical

reactions in gaseous mixtures of uranium-hexafluoride and hydrogen-chloride. In his experiments Eerkens used a carbon dioxide (CO₂) laser of his own design, with a wave length of 10 microns. The results he obtained were validated by Garrett mass spectrometry specialists; their measurements indicated that Eerkens had achieved a separation factor³³ of 1.01³⁴. That was better than the 1.004 factor of the gaseous diffusion technology, which was the prevailing enrichment method at the time.³⁵ The experiment was repeated several times, delivering consistent results.³⁶ Eerkens believed that the technology could be further improved to achieve a separation factor of 1.1-1.5. To illustrate, the IR-1 gas centrifuge, which currently forms the core of the Iranian nuclear enrichment capability, has a separation factor of about 1.3.³⁷

Citing these results, Garrett corporation applied to the Atomic Energy Commission for funding. The application was passed on for technological vetting to the Los Alamos National Lab, which was the lead US organization for the research of molecular laser isotope separation. Los Alamos specialists concluded, however, that the proposed uranium enrichment technology was not viable. Based on that conclusion, AEC denied funding for further research. For the same reason it was decided that there was no point classifying the technology. The delicacy of the situation was that the job of assessing the technology proposed by Eerkens was given to a laboratory which was receiving generous state funding for the research of molecular laser separation method. It would be no stretch to imagine that the Los Alamos Laboratory probably saw Eerkens' technology as a competitor to its own research.

Nevertheless, AiResearch continued to fund Eerkens' experiments from its own budget. Several months later it made another application to the Atomic Energy Commission, but the request was denied once again. The AEC recommended that Garrett stick to developing the gas centrifuge technology, a project funded by the Commission itself. In late 1975-1976 AiResearch decided to discontinue its laser enrichment efforts. One of the reasons for the decision was the company's unwillingness to plough its own money into a project directly competing with a similar program of the Los Alamos Laboratory, especially since the work of its rivals was being heavily funded by the government to the tune up to 30m USD a year. In addition, differences broke out between the Garrett management and Eerkens over the timing and the size of royalties to be paid to him for the use of his patented technologies.

On December 11, 1975 Eerkens filed a second CIP (= Continuation-in-Part) patent application for a laser-based method of separating the isotopes of heavy elements, which he called LISOSEP.^{38,39} The patent application contained a description of the separation technology and of a uranium enrichment plant using that technology. According to that description, the plant is capable of enriching natural uranium to 2.5%-7% level in a single cycle (which translates into a separation factor of 4-10). The estimated cost of separation using such a plant was said to be just 0.1%-1% of the corresponding figure for a plant based on the diffusion technology.⁴⁰ The figures stated in the patent application were obtained by theoretical calculations and had not been confirmed by experiments. Eerkens deduced in later years that most of the

chemical harvesting techniques described in the patent were unachievable, and that only the suppression of dimer formation (his “Plan B”) could lead to successful economic uranium enrichment⁴¹.

Eerkens was unhappy with the way the laser project was being handled by AiResearch. More specifically, he was concerned about the company's failure to win extra funding for further research, the slow pace of the project, and the need to share his time between the gas centrifuge and the laser project. As a result he began to look for other parties which might be interested in exploring the laser enrichment technology.⁴²

The letter to the Shah of Iran

Eerkens undertook energetic efforts to spread the word about his laser research. On January 2, 1976 he submitted an article describing his experiments at AiResearch and the results he had achieved to the journal *Applied Physics B: Lasers and Optics*. The article was accepted and published in the May 1976 issue of the journal.⁴³ In June 1976 Eerkens delivered a report at an international conference on quantum electronics in Amsterdam. Shortly afterwards he held a presentation at the French Nuclear Research Center at Saclay.⁴⁴

In an effort to find customers and investors for his uranium enrichment technology, Eerkens investigated various new potential funding sources. Having failed to secure support and financing for his research from American companies and government agencies, Eerkens began to think about potential foreign investors. One of the first persons he contacted was a vice president of Royal Dutch Shell, Mr. Toxopeus. Shell was looking into diversifying its business at the time. In 1974 it acquired a 50-percent stake in General Atomics⁴⁵. But the European oil giant’s specialists who arrived in San Diego, California, to discuss opportunities for cooperation showed no interest in Eerkens’ technology.⁴⁶

A friend of Eerkens’, an entrepreneur from Florida named Don Watson, proposed that funding should be sought from the Libyan ruler, Col. Muammar Gaddafi, who declared in the late 1970s that he was willing to spend up to 10bn USD on developing nuclear technologies in his country⁴⁷. But Eerkens rejected the idea⁴⁸.

Then help arrived from unexpected quarters. In the early 1930s Jan Boost, Eerkens' uncle, taught the German and French languages to the Iranian Shah, Mohammad Reza Pahlavi, when the latter studied at Institut Le Rosey, one of Switzerland’s most prestigious boarding schools. Eerkens told that story to Iranian businessman Sassan Safa, who made a living by exporting American electronics to Iran. Safa immediately said that, given the role Eerkens’ uncle had played in the education of Mohammad Reza Pahlavi, the scientist should apply for funding for his laser enrichment research to the Shah of Iran, who was known for his support for high-tech projects. Ted Farrell, a friend of Eerkens who was present at the conversation, expressed his doubts about the idea. He argued that the Shah had just given France a 1bn USD loan to build a gas diffusion uranium enrichment plant as part of the Eurodif international consortium.⁴⁹

But the Iranian businessman said he would draft a letter to the Shah, which Eerkens signed and posted on February 11, 1976.⁵⁰

The letter mentioned the LISOSEP laser enrichment technology developed by Eerkens. It said that based on the experiments conducted in 1972-1973, the technology promised to be much more economical than all the existing alternatives, including gas centrifuges. The letter argued that a commercial-scale uranium enrichment plant based on the laser technology would cost only 100m USD, i.e. about one-twentieth of the cost of the plant based on the gas diffusion technology. Eerkens attached to the letter his resume and a list of his published papers to demonstrate his scientific credentials. The letter was addressed to “His Imperial Majesty, the Shah of Iran, Tehran, Iran”.⁵¹

Eerkens did not have any great expectations from the letter – but two weeks later he received first a telegram and later a phone call from Mojtaba Taherzadeh, head of the Tehran Nuclear Research Center. That is how Eerkens' career path became intertwined with the Iranian laser enrichment program.

TNRC director Mojtaba Taherzadeh obtained a PhD from the University of California in 1964 and became a US citizen. He had spent a long time working for the American defense industry.⁵² Prior to his return to Iran he took part in a project to develop space-borne nuclear reactors (SNAP)⁵³ at the Jet Propulsion Laboratory. In an interesting coincidence, Eerkens participated in the same project in the late 1950s when he was preparing his doctoral thesis and working for Aerojet-General-Nucleonics, AGN. Taherzadeh invited Eerkens to visit Tehran, with the Iranian side paying the costs, and to discuss cooperation.

Jeff Eerkens' Iranian project

Eerkens requested the consent of the US Department of Energy, the successor of the AEC, to discuss the possibility of cooperation with the AEOI in implementing his laser enrichment technology. But the DOE Division of Classification and the Office of Advanced Isotope Separation expressed serious proliferation concerns and voiced their objections. After consulting his lawyer Eerkens withdrew his request for DOE consent, since according to the legal advice he had received, he did not actually require any official approval to hold consultations in Tehran.⁵⁴

In the fall of 1976 Eerkens took several days' leave at AiResearch to visit Tehran and discuss the terms of cooperation with Iranian scientists to develop further his LISOSEP uranium enrichment technology. Eerkens obtained the Iranian entry visa right at the Tehran airport after informing the border officials that he had been invited to the country by the AEOI.⁵⁵ After passing all the border and customs formalities he was met at the airport by TNRC Director Mojtaba Taherzadeh.

During that visit to Tehran Eerkens held talks with senior Iranian nuclear officials, including AEOI President Akbar Etemad, TNRC Director Mojtaba Taherzadeh, and TNRC Laser Technology Division Chief Ehsanollah Ziai, who later became one of

Eerkens' main negotiating partners.⁵⁶ The vast majority of the scientists who took part in the meetings were US-educated and spoke fluent English, so there was no language barrier. Dr. Ziai was educated at the University of Southern California, but returned to Iran and joined the TNRC when the Shah announced the launch of an ambitious nuclear program. During his stay in Tehran Eerkens also visited the Iranian nuclear research facilities and met TNRC scientists. In particular, he was given a tour of the TNRC laboratories and the TRIGA⁵⁷ research reactor, which was designed by General Atomics. He was impressed by the rapidly growing Iranian capital, with its bustling construction sites and new office centers hosting the local branches of transnational corporations. At the invitation of one of the TNRC staff members Eerkens attended a Tehran Opera performance at the Rudaki concert hall, and was greatly impressed by what he saw.⁵⁸

One of the main outcomes of Eerkens' visit to Tehran was the AEIO's consent to finance further research into LISOSEP laser enrichment technology and an agreement to build a laser enrichment laboratory based on that technology at the TNRC Laser Technologies Division. The plan was that all further research would be conducted simultaneously in Iran and the United States, and that a total of six experimental laser enrichment units would be made, each consisting of the laser, the ancillary optical equipment and the irradiation chamber. Four of those units were to be delivered to the TNRC and two installed at the Lischem laboratory in California. According to Eerkens' calculations at that time (which had not been experimentally tested prior to the signing of the contract with the Iranians) each of the four lasers was capable of producing up to 1kg of uranium enriched to 5 per cent every day, using natural uranium (which has 0.71 per cent U-235 content) as the source material.^{59,60} Eerkens believed that having a similarly equipped laboratory in the United States would make it easier to obtain the high-tech hardware needed for the project.

The priority for TNRC was to improve the LISOSEP technology in order to explore its possible uses in the future on an industrial scale. The tentative plan for the longer time frame was to build an enrichment facility using the new method of producing low-enriched uranium for nuclear fuel in addition to the separation capacity of the gas-diffusion enrichment plant in Tricastin (France), in which Iran held a 10-per-cent stake.⁶¹ A report released in June 1977 by the U.S. Congressional Office of Technology Assessment said that at some point in the future Iran could potentially become an exporter of uranium enrichment services.⁶²

Upon his return to California Eerkens told his bosses at AiResearch about the outcome of the talks in Tehran. He invited the company to join the implementation of the agreements reached with the Iranians, which would enable him to use the existing infrastructure and hardware at AiResearch. But the company's bosses rejected the proposal and were unhappy with the very idea of Eerkens holding the talks in Iran. They declined the AEIO's offer of financing for further research into laser enrichment. But, according to a conclusion made in 1980 by the General Accounting Office, Eerkens had not broken any U.S. laws by visiting Tehran and holding talks with the AEIO.⁶³

After his proposals were rejected by AiResearch, Eerkens once again became convinced that there was no alternative to setting up his own company. On November 24, 1976, he and his colleague Titus Nelson, who was interested in making lasers for consumer applications (mainly for laser engraving), registered the Lischem company in Miami, Florida. The name Lischem stood for Laser Isotope Separation and Chemistry.⁶⁴ The company had a small industrial building in Lawndale, California, near the LA International Airport and only a few miles from the offices of AiResearch, which Eerkens continued to work for until April 1977. The money to set up Lischem was raised with the help of Don Watson, the already mentioned entrepreneur from Florida. Watson agreed to invest his own money and found six private investors in Florida willing to contribute a total of 50,000 USD in return for a stake in the new company. By October 1976 Eerkens had assembled a group of six scientists and engineers, most of whom had already worked with him before. Several weeks later they were officially hired by Lischem to become the company's first employees.

In the spring and summer of 1977 Eerkens and TNRC director Mojtaba Taherzadeh had two meetings in Los Angeles, not far from where Eerkens lived, to discuss the details of the project to build a laser enrichment laboratory in Iran.

During the meetings the two sides reached an agreement in principle on three main areas. First, they agreed that the project would be implemented in two phases. The first phase was to include the manufacture and delivery to Iran of the necessary equipment: four carbon monoxide lasers (LCL-516 model, 25W), and four irradiation chambers (LCR-350 model). The agreed specifications of the experimental laser enrichment unit included irradiation chambers made of nickel, a corrosion-resistant material, to make sure that the chamber could work with halogen gases, and a special design of the unit to enable it to be easily disassembled if the need arose.⁶⁵

During the second phase of the project Eerkens was to travel to Tehran and bring with him the optical equipment for the laser enrichment laboratory (which was small enough to fit into carry-on luggage). He was to provide technical assistance during the installation and launch of the equipment, and during the first two years of its operation. The plan was for Eerkens to move to Iran and to bring his family with him.⁶⁶ The overall value of the contract was 2.35m USD, of which hardware accounted for 630,000.⁶⁷ The cost of the services and equipment was based on figures from the Lischem product catalogue.

The second agreement, which was proposed by Taherzadeh, was that the equipment for the laser enrichment laboratory would be supplied to Iran via Gifted, Inc., which would act as Lischem's export agent. Gifted was founded by Naim Perry, a US-Iranian businessman. Perry was making most of his money on property investment; he was the president of Properties Management and Diversified Development, Inc. He and his wife were also the co-founders of Gifted, Inc., which specialized in exports and imports of high-tech products. Perry had already had some business dealings with the AEOI, and unlike Eerkens he had already had a lot of experience in obtaining US export licenses for high-tech equipment⁶⁸.

One of the terms of the deal on which Perry had insisted was that he should be allowed to be the only capital investor in Lischem. All existing shareholders agreed to sell their stakes at a 10-per-cent premium less than a year after making the original investment. Lischem was then re-registered in California in July 1977. Naim Perry received full control over the company's finances.

Under the agreement reached with the Iranians, the AEOI was to pay for all the equipment to be supplied to Iran directly to Gifted, Inc. Commercial dealings between the two sides were based on pro forma invoice No 4080 of July 6, 1977 submitted by the US company to the AEOI, and irrevocable letter of credit No 08/92282 of November 15, 1977, issued by the Iranian central bank (Bank Markazi) at the request of the AEOI.⁶⁹ Gifted then signed a subcontract with Lischem to produce the required equipment. Later on there were two addendums to the letter of credit. Under the first addendum, the expiration date of the letter was extended until November 15, 1978. Under the second, the equipment was to be supplied in two batches (two sets of equipment in the first batch and another two in the second batch.)⁷⁰

Third, the Iranian side was interested in buying lasers with a wave length of 16 microns, which are ideally suited for use in uranium enrichment. Under the terms of the preliminary agreement reached in Tehran, such lasers were to be supplied.⁷¹ But Eerkens was forced to admit that at that time, he did not have the technology to make lasers of that wave length. That is why he proposed - and the Iranians accepted - that to obtain the required system specifications, they would use 25W carbon monoxide lasers with a wave length of 5 micron⁷², coupled with a carbon tetrafluoride wave length converter. The combination produced the required laser radiation with a wave length of 16 microns, to achieve the optimum efficiency of the enrichment process. The lasers were of 'flexible design', i.e. the carbon monoxide they used as the active material could be replaced with another gas, thereby changing the properties of the laser.⁷³

Eerkens made another visit to Tehran in early 1978 in order to discuss the final details of his work at the TNRC as part of providing assistance in the installation and operation of the experimental laser enrichment units. He also needed to arrange his and his family's relocation to Tehran, including housing and the choice of an international school for his children.⁷⁴

Licensing of the export of laser equipment to Iran

On February 7, 1978 Gifted applied to the Department of Commerce for a license to export four lasers and related equipment to Iran. In accordance with US laws, the application contained information about the intended use of the equipment to be supplied, which was stated as 'laboratory plasma research'. The equipment to be exported, i.e. the experimental laser enrichment units, relied on technology which was not classified by the DOE, so the company decided to declare a broader scope of its application so as to simplify the procedure and expedite the licensing process. The application did not specify that the intended use of the equipment to be exported was to enrich uranium.⁷⁵ This made for a simpler procedure for the review of the

application, bypassing the more intrusive aspects of it and the need for personal vetting by the Secretary of Energy (James Schlesinger at the time). Neither did the application for export license state the power output of the lasers to be supplied.⁷⁶

Just when the application was being processed, the US Congress passed the 1978 Nuclear Nonproliferation Act, which tightened controls over the exports of technologies which could potentially be used for building nuclear weapons.⁷⁷ In accordance with the new Act, if the DOC and the DOE believed that that the application for export license should be denied or reviewed further, they were to submit that application for the consideration of a special interagency group. The group included representatives of the Department of State, the Department of Defense, the DOE and the DOC, the Arms Control and Disarmament Agency, and the Nuclear Regulatory Commission.

In accordance with the established procedure, the application filed by Gifted was passed on to the Department of Energy. After reviewing the application, on February 14 a DOE expert instructed the Department of Commerce not to issue the license for the time being, and to submit the application to the DOE for closer scrutiny. According to the expert, he made the decision after becoming suspicious about the unusually high price of the equipment stated in the application.⁷⁸

On March 17, 1978 the DOE sent the application for technical review to three DOE-related organizations: the DOE Office of Laser Fusion, the DOE Office of Advanced Systems and Materials Production, and the Lawrence Livermore National Laboratory, which was researching the atomic vapor laser isotopes separation (AVLIS) technology at the time. The DOE decided not to involve experts from the Los Alamos National Laboratory, which was the lead US organization for molecular laser isotope separation (MLIS) technology, and which had already conducted an assessment of the laser enrichment technology developed by Eerkens when he worked for Garrett corporation. On March 23 and April 5 the first two organizations informed the DOE that they had no objections against the export license application. The Livermore Laboratory requested additional technical information about the lasers to be exported; the laboratory's experts believed that such information should have been provided in the original application. There is no definitive information about the final conclusion made at Livermore. According to DOE officials, the response from the laboratory said there were no reasons to reject the export license application, but these officials could not provide any documentary evidence. Meanwhile, representatives of the Livermore Laboratory say they have never issued any official conclusion on the matter because they had received incomplete technical information about the equipment to be exported.

On June 13, 1978, based on the conclusions made by its specialists, the DOE returned to the DOC a recommendation that the requested export license should be granted because the equipment to be exported posed no nuclear proliferation risk. On June 20 Gifted received a DOC license to export to Iran the four lasers and related equipment for use in laboratory plasma research.⁷⁹

The present author has failed to identify a definitive answer to the question of why the export license application was approved, even though DOE officials had previously objected to Eerkens' discussing the project with the AEOI and expressed serious proliferation concerns. The explanation probably includes a whole host of various factors, including commercial, political and technological. Imperfections of the export licensing process also seem to have played a role.

The United States and Iran had spent several years in difficult talks on the agreement on peaceful nuclear energy cooperation (the 123 Agreement) before the document was finally initialed on July 10, 1978.⁸⁰ One of the most contentious issues during the consultations was the development of sensitive elements of the nuclear fuel cycle on Iranian territory. The American nuclear industry had pinned great hopes on the large Iranian market. It also saw Iran as a potential source of large investment, including investment in projects to build new uranium enrichment facilities.⁸¹ For example, Westinghouse hoped that the government in Washington would help American companies to win 75 per cent of the world market for exports of nuclear power plants by 1982.⁸² The company had plans to build six to eight energy reactors in Iran.⁸³ On June 30, 1974 the AEOI and the US Atomic Energy Commission signed two preliminary contracts for the supply of nuclear fuel.⁸⁴ In that context, a refusal to grant a license for exports of laser equipment to Iran could adversely affect the progress of the talks and the commercial prospects of American companies in the Iranian market, where Germany's Siemens and France's Framatom were already present. Some US government experts viewed supplies of sensitive American materials and technologies to Iran, including HEU, as a way of strengthening America's reputation as a reliable nuclear exporter and of encouraging Iran to choose American companies for multi-billion-dollar contracts to build NPPs in the country.⁸⁵

Also, amid the increasingly tense domestic political situation in Iran and a growing wave of protests against the rule of the Shah, who was viewed by Washington as a key ally in the Gulf region, it was important for the Carter administration to demonstrate its staunch support for Mohammad Reza Pahlavi and his regime. The last thing the Americans wanted was to undermine the already weak rule of the Iranian monarch.⁸⁶ A refusal to issue the export license, had it been leaked to the public domain, would have been seen by the supporters and the opponents of the Iranian regime as a sign that the White House was abandoning the Shah, and that America was ready to work with the opposition forces. After turmoil began in Iran, the government in Washington took this consideration into account when deciding whether to remove over 5kg of 93-percent enriched uranium of US origin from the Tehran Research Reactor.⁸⁷

It is also likely that the decision to issue the export license was influenced by Washington's skepticism about the usability of the laser technology for uranium enrichment. In 1973-1974 the US Atomic Energy Commission decided that there was no reason to classify the information about Eerkens' first experiments and achievements in molecular laser enrichment made when he was working for AiResearch. In the late 1990s, when new reports appeared about Iran's intention to buy laser equipment suitable for use in uranium enrichment, most American scientists

spoke condescendingly about the Iranians' interest in that technology. They thought it a waste of time, and viewed laser enrichment as a dead end as far as the separation of uranium isotopes is concerned.⁸⁸

Also, according to a report released by the US Government Accountability Office on March 17, 1980, the DOE's examination of the export license application filed by Gifted, Inc. was not sufficiently comprehensive. The report reads that the DOE had failed to request the necessary additional information from the applicant, including information about the power output of the lasers to be exported, and that it did not contact the manufacturer, Lischem, for details about the intended use of the equipment.⁸⁹ In addition, the DOE's recommendation to the DOC to issue the export license to Gifted, Inc. appears to have been made before the DOE had received the conclusions of the Lawrence Livermore National Laboratory, which had been asked to conduct technical analysis of the export license application. Neither did the decision to issue the license involve specialists of the Los Alamos National Laboratory, which was the lead organization for the research of molecular laser enrichment. Finally, the DOE had failed to establish that the founder of Lischem, Jeff Eerkens, had previously been involved in classified US government programs to develop the gas centrifuge technology of uranium enrichment.⁹⁰

Turmoil in Iran: delivery of the laser equipment

The economic and domestic political situation in Iran had changed a lot in the period between Eerkens' visit to Tehran in early 1978 and the moment when Gifted, Inc. received the export license.

The country was facing a spiraling political and economic crisis. Ordinary Iranians, who regarded Iranian oil as their national wealth, did not see any changes for the better in their lives even as Iran's oil export revenues were growing at a breakneck pace.⁹¹ There was pervasive corruption, which affected even the top tiers of the government, and growing discontent with the ruling regime. Most of the Iranians wanted radical changes. In 1978, amid growing inflation, falling real incomes and widespread discontent over the government's social policies, the country was plunged into turmoil. In May-June 1978 it saw the first open protests against the Shah's regime, which quickly degenerated into rioting in Tehran and other major cities.⁹² On September 8 the government declared martial law in Tehran and 11 other cities. It sent tanks to the capital's international airport to bolster its security and protect critical infrastructure. Mass anti-Shah protests paralyzed the whole country in September-October 1978.⁹³ On January 16, 1979, Shah Mohammad Reza Pahlavi gave up his attempts to cling on to power and left the country.⁹⁴

The year before the fall of the Shah regime the Iranian government, facing a massive budget deficit, was forced to review its energy diversification program. It declared a moratorium on signing new contracts for the construction of NPPs.⁹⁵ Soon afterwards it cancelled several nuclear projects for which it had already signed contracts. In late 1978 it froze the construction of the Esfahan Nuclear Technology Center, which was being built with the assistance of French specialists. In January 1979 Iran cancelled

the contract for the construction of nuclear reactors in Darkhovin with France's Framatome, citing lack of financial resources. In July 1979 Germany's Siemens suspended construction at the site of the Bushehr NPP after Iran ran up large debts for the work which had already been delivered. In September 1978 AEOI President Akbar Etemad quit his job, and the organization lost its independent status, becoming a division of the Ministry of Energy.⁹⁶ On November 8 Amir Abbas Hoveyda, who had served as the Iranian prime minister for many years and who was one of the main proponents of nuclear energy in the Iranian government, was taken into custody.⁹⁷

In July 1978 the Iranian Desk at the US Department of State concluded that the fall of the Shah's government in Iran was inevitable. In October 1978 the DOS decided to establish contacts with Khomeini and his supporters in Paris. Nevertheless, some senior US officials, including Zbigniew Brzezinski, the national security advisor in the Carter administration, continued to consider possible ways of perpetuating the Shah's regime well into December.⁹⁸

Shortly after Gifted, Inc. had received the export license in June 1978, the company informed the AEOI that the equipment was ready to be shipped. It asked Iran to send two specialists to the United States to certify the lasers, as previously agreed. But by that time the AEOI had already lost interest in the laser enrichment laboratory. Iran asked Gifted, Inc. not to supply the equipment.⁹⁹ In order to formally discharge its contractual obligations and recoup the money invested in making the hardware, the US company invited an independent expert, an electrical engineering professor from the University of Southern California, to rate the output of the lasers it had made. The expert's measurements put the output of the lasers at 26W (under the agreement, the figure should have been at least 25W).¹⁰⁰ The equipment was then shipped to Iran on November 8, the day when former Iranian prime minister Hoveyda was taken into custody¹⁰¹, and a week before the expiry of the letter of credit issued by the Iranian central bank at the request of the AEOI. The equipment included two lasers and two irradiation chambers. It was packaged into eight crates weighing over 3 tonnes, and sent to Tehran on an Iran Air flight¹⁰². Another two sets were shipped to Iran later¹⁰³.

The original plan was to make six sets of the equipment. In actual fact, however, Lischem had made only "five and a half" sets - namely, five laser systems and six irradiation chambers. Four of these sets were supplied to Iran; the remaining laser and two chambers were later installed in a Lischem workshop in California.¹⁰⁴

After mass protests broke out in Iran the State Department issued a warning that it was no longer safe for Americans to travel to the country. Eerkens and his family were in the Netherlands at that time, waiting for the situation in Iran to return to normalcy. He had with him the optical equipment for the experimental laser enrichment units. Eerkens spent more than four months waiting, but after the Shah left Iran, he was forced to return to California. The new Iranian leadership showed no interest in continuing the nuclear projects launched under the Shah. Eerkens unsuccessfully tried to contact Taherzadeh to find out what had happened to the equipment already sent to Tehran. But the former TNRC chief had already left Iran;

he fled to the United States by way of Turkey. The former AEOI president, Akbar Etemad, emigrated to France¹⁰⁵.

The Iran–United States Claims Tribunal: the laser affair

After the equipment was shipped to Iran, Gifted, Inc. attempted to claim the payment; the company believed that it had fulfilled its obligations under the contract with Iran. But the new Iranian leadership refused to honor the letter of credit issued by the central bank under the old regime. Gifted, Inc. and Lischem filed a claim at the International Court of Justice in The Hague. The sides attempted to reach a financial settlement out of court; there was a meeting in London between Gifted, Inc. representatives, the company's lawyers and Eerkens on the one side, and the AEOI on the other. The Iranians offered to pay 10 per cent of the contractual price of the equipment supplied by Gifted, Inc. The company rejected the offer¹⁰⁶. The Iranians then said they were willing to return the equipment back to the US; the company rejected that, too.¹⁰⁷ The case was then brought before the Iran–United States Claims Tribunal, which was set up in 1981 in accordance with the Algiers Accords to settle claims involving the two countries, their citizens, companies and organizations.¹⁰⁸

The hearing was conducted in The Hague by three judges representing Iran, the Netherlands, and the United States. The Tribunal upheld the American plaintiff's claim and ordered the AEOI to pay Lischem the full sum agreed under the contract, 630,000 USD, plus a late payment surcharge at 12 per cent interest calculated starting from the date of expiry of the letter of credit. The court refused to consider Gifted, Inc. as a plaintiff because more than 50 per cent of its shares were held by non-US citizens, meaning that its claims fell outside the Tribunal's remit. The Tribunal concluded that Lischem had discharged its contractual obligations and announced its ruling in favor of the company on June 22, 1984, i.e. more than five and a half years after the equipment was shipped to Iran. The money was paid from a special Security Account set up by Iran and the United States at the Dutch Central Bank when the Tribunal was created. Of the Iranians who negotiated the deal with Eerkens in 1976-1978, only the head of the TNRC Laser Technology Division, Ehsanollah Ziai, and a senior expert of the Division, Reza Khonsari Mosavi, were involved in the Tribunal proceedings.¹⁰⁹

In a written statement by the Tribunal, one of the three presiding judges noted that there were serious signs of fraud and bribery in the agreement reached between Gifted, Inc. and the AEOI. But the two other judges did not support the proposal to hold a special inquiry into these claims. A DOE representative who reviewed the Gifted, Inc. export license application in 1978 also noted that the price of the contract between the company and Iran was suspiciously high.¹¹⁰ Two former Lischem engineers also testified that the agreement reached between Gifted, Inc. and AEOI included cash payments to Iranian representatives in return for facilitating the transfer of funds into the company's accounts.¹¹¹ But these allegations did not become the subject of any official investigation, and Naim Perry, the founder of Gifted, Inc., flatly rejected them.

It should be said that in view of the ruling of the Tribunal, some of the wording used in the IAEA Director General's report entitled 'Implementation of the NPT

Safeguards Agreement in the Islamic Republic of Iran' of November 10, 2003, appears imprecise. The report says, in particular, that the execution of the contract was 'ultimately terminated'¹¹². In actual fact, cooperation between the AEOI and the Gifted-Lischem tandem did not continue (as was previously planned) after the equipment was delivered, but the American suppliers had fulfilled their side of the contract; the verdict of the International Court is very unambiguous about that.

Laser enrichment in Iran after the Islamic Revolution

The equipment supplied to Iran is believed to have spent more than six months (at least until the summer of 1979) at the customs transit warehouse at Tehran airport because the new Iranian leadership was showing no interest in pursuing a nuclear program. Later on the lasers and the ancillary equipment was brought to its intended destination, the Tehran Nuclear Research Center, where it sat in its shipping crates until late 1983.¹¹³ Iranian specialists finally made an attempt to install the hardware only in the mid-1980s, more than five years after the cargo was delivered, when the Iranian government decided to resume its nuclear programs and uranium enrichment research. Iran attempted to manufacture the missing parts of the enrichment unit, which were never supplied by Gifted, Inc. – but, to the best of our knowledge, to no great avail.¹¹⁴

After the outbreak of mass protests in Iran in early 1978 - and especially after Mohammad Reza Pahlavi's departure from the country in early 1979 - several countries which were cooperating with the Shah's regime in the area of military and dual-use technologies began to evacuate their equipment, documents, advisors and specialists. Some of the first to leave in June 1978 were the Israeli engineers working on the Flower project, a joint Iranian-Israeli effort to develop a surface-to-surface missile.¹¹⁵ According to Israeli experts, all the project documents were also removed from Iran.¹¹⁶ In October 1979 the US government managed to secure the consent of the transitional Iranian government for the removal of sensitive electronic equipment from advanced fourth-generation F-14 fighters previously supplied by the United States. In return, Washington agreed to resume the supplies of aircraft spare parts.¹¹⁷ American officials were also looking into the possibility of removing HEU fuel of US origin from the Tehran Nuclear Research Center.

It appears, however, that the US government made no efforts to remove from Iran the equipment supplied for the laser enrichment laboratory by Gifted, Inc., even though the deal had been criticized by some experts at the US Arms Control and Disarmament Agency and at the national nuclear laboratories.¹¹⁸

After Iran resumed research into laser separation of uranium isotopes, it focused on the atomic vapor laser isotope separation technology (AVLIS) using equipment supplied by Germany and China.^{119,120} Formidable resources were invested into that technology¹²¹. In the late 1990s Iran approached Russian research institutes which make laser equipment with offers of cooperation¹²². It also had contacts with French and South African organizations¹²³, and bought from Australia mass spectrometers which were later used to provide analytical services (isotope enrichment

measurements).^{124,125} According to Eerkens, he has never been approached by the new leadership of the Iranian nuclear industry with any offers to resume cooperation on the molecular method of laser enrichment.

With Chinese assistance, the TNRC Laser Research Center (apparently created from the old Laser Technology Division) set up a Laser Spectroscopy Laboratory (LSL) and a Comprehensive Separation Laboratory (CSL) to conduct research into AVLIS as a method of uranium enrichment¹²⁶. The building where the two labs were located also housed the equipment designed by Eerkens. After making first contacts with his Iranian counterparts, the Russian nuclear energy minister, Victor Mikhailov, noted that the AEOI regarded laser technologies as an important priority for nuclear industry development, and that the research undertaken by the Iranians in the field was on a large scale.¹²⁷ It was later reported that the atomic vapor laser isotope separation technology had enabled Iran to enrich uranium to a maximum level of 13 per cent.¹²⁸ These activities were not properly declared to the IAEA.

In May 2004, after the IAEA began investigating Iran's undeclared nuclear activities, Tehran announced that it had discontinued the laser enrichment program. It informed that the equipment was dismantled in May 2003 and moved to a warehouse at the Karaj Agriculture and Medical Centre.¹²⁹ That claim was later verified during a visit to the site by IAEA inspectors. On February 7, 2010 the Iranian president, Mahmoud Ahmadinejad, announced that Iran possessed laser enrichment technology. As of July 2012, Iran has not provided any official explanations for that statement.¹³⁰ It confirmed, however, that it continued to pursue laser research¹³¹.

As for the equipment supplied by Gifted, Inc, the Iranians said that because some of the components were missing, the laboratory was never fully operational¹³². In October 2003 IAEA specialists inspected the presumed premises where the equipment for MLIS technology research was located. According to one of the agency's specialists, the irradiation chambers he was shown really did look as though they had never been used. According to the same source, environmental sampling also failed to detect anything suspicious.¹³³ But because neither the United States, nor Iran had supplied any comprehensive information about the equipment delivered in 1978, the IAEA inspectors had no way of knowing whether the irradiation chambers they saw were the same chambers that were supplied by Gifted, Inc.¹³⁴

During their investigation of Iran's undeclared nuclear activities, IAEA inspectors did not have an opportunity to interview Eerkens officially (although they did speak to him in private capacity at various science conferences)¹³⁵. The US government supplied the missing details in the mid-2000s by giving the IAEA information about Eerkens' cooperation with the AEOI.¹³⁶ The FBI and the US customs service had already investigated Eerkens, Lischem and Gifted, Inc. for possible violations of US laws back in the early 1980s.¹³⁷ But the findings of those investigations were never released into the public domain. Information about the equipment for a laser enrichment laboratory supplied by Gifted, Inc. to Iran was provided to the IAEA more than 20 year after the investigation.

In parallel with AVLIS research, in the mid-1980s the new Iranian government decided to prioritize the development of the gas centrifuge enrichment technology, which had already reached a degree of maturity in some other countries, and for which Iran could find assistance abroad (namely, in Pakistan). All the low-enrichment uranium which Iran has produced in substantial quantities, and which has now been placed under IAEA safeguards, was enriched using the gas centrifuge technology. Centrifuges were also used to produce the uranium enriched to 20 per cent, which is the highest level of enrichment Iran has achieved so far.¹³⁸

The Eerkens technology: afterword

Immediately after the conclusion of litigation with the AEOI and payment of the compensation awarded by the Tribunal, Naim Perry ended his cooperation with Lischem. Eerkens, meanwhile, continued to research the laser method of heavy isotopes separation using private financing. At a laser technology exhibition he met Dick Griot, owner of Melles-Griot, a large maker of optical and laser equipment. In 1980 the company signed a strategic partnership agreement with Lischem and undertook to finance Eerkens' research.

In 1985 Griot bought Lischem and the rights to the patents held by Eerkens. He founded a new company, Isotope Technologies, Inc. (ITI). Eerkens became the owner of a 30-per-cent stake in ITI. The main goal of the company was to develop a commercially competitive technology of laser enrichment of uranium. The LISOSEP technology was renamed to CRISLA.¹³⁹ ITI began to look for a large strategic investor.

Australia was one of Melles-Griot's strategic markets. That is where Dick Griot met Michael Goldsworthy, founder and president of Silex¹⁴⁰, which was also developing a laser technology of uranium enrichment. Goldsworthy visited Los Angeles and the ITI laboratory; in 1988-1990 the two companies began to exchange science and research data. They negotiated a merger and were on the verge of setting up a joint venture in California. Silex and ITI lawyers had even prepared all the necessary documents - but two days before they were due to be signed Dick Griot called the deal off after receiving information from an agent in Sydney that Silex was unable to invest sufficient resources of its own into joint projects.¹⁴¹ Silex and Jeff Eerkens parted company. Almost 20 years later, in 2007, the Australian company made headlines after signing an exclusive deal with General Electric to commercialize its laser enrichment technology.

ITI, meanwhile, found a large investor in 1990. A joint venture was set up with Canada's Cameco, the world's largest producer of uranium at the time. ITI equipment was relocated from Los Angeles to Saskatoon, Saskatchewan Province, where the Canadian corporation kept its HQ. Cooperation with Cameco ended three years later, in 1993, when significant quantities of Russian low-enriched uranium became available on the commercial market after the fall of the Iron Curtain.¹⁴² Cameco decided that it made better commercial sense to become a reseller of Russian uranium (the arrangement did not work out in the end) rather than to continue investing in its

own enrichment technology.¹⁴³ In 1993 the Cameco Board of Directors voted down, by four votes to three, a three-year, 50m-dollar program of developing the CRISLA technology.¹⁴⁴

All the equipment which had already been installed at Cameco was returned to ITI. Dick Griot, who had already retired by that time, decided to give the equipment to his alma mater, the University of Missouri. For the first time since he moved to the United States in 1950, Jeff Eerkens was forced to leave California and relocate to Missouri. Ten years later, after completing his stint as an adjunct professor at the University of Missouri, he returned to California and took his equipment with him.

Eerkens holds more than 15 patents for inventions related to the laser technology of uranium isotope separation and for other innovations. These patents are valid for 17 years each, so most of them have already expired.¹⁴⁵ In 1995 Eerkens published a 728-pages book entitled 'Laser Isotope Separation', which WalMart sold for 95.40 USD a copy.¹⁴⁶ The book is now available from Amazon.com for 114 USD.

The first batch of the experimental laser enrichment equipment made by Eerkens for AEOI is now at the Karaj Agriculture and Medical Centre. Eerkens keeps the second batch (the laser, the optical system and two irradiation chambers) in a warehouse near San Francisco, California. Ironically, before being returned to California the equipment was stored in open barns at the College of Agriculture, Food and Natural Resources (a division of the University of Missouri).

Eerkens now has a new company, Prodev Consultants, and continues to look for opportunities for further improvement of his CRISLA technology. He believes that it can successfully compete with the Silex laser enrichment technology, which is now being commercialized by two giants of the global nuclear industry, GE-Hitachi and Cameco. Eerkens is convinced that his "Plan B" CRISLA technology approach, whose proof-of-principle was experimentally demonstrated in his 1986 tests¹⁴⁷, can produce reactor-grade uranium (3-5 per cent enrichment) in just two cycles, compared to the 5-10 cycles required by the gas centrifuge technology. He estimates the required initial investment at 2 million dollars.¹⁴⁸

- ³³ The separation factor is one of the key characteristics of any uranium enrichment technology. The higher the exceedance of the separation factor over one, the more effective the technology is. A low separation factor can be compensated for by passing the material being enriched through several stages (cycles) which form an enrichment cascade. For example, the enrichment plants which rely on the gas diffusion technology contain thousands of enrichment stages and are housed in buildings several hundred meters long.
